

Validation Set Approach

1. Split data
2. Train model on training set
3. Evaluate train and test set

data

The test error is the average error resulting from using a method to predict a response on a new observation that was not used when training the method

The training error

- ▶ is computed by applying SL method to observations when training the method
- ▶ often very different from test error rate and underestimates the test error rate

Our validation approach so far...
